Research Design for Social Sciences
MA Computational Social Science, UC3M
Fall 2024

A real example

- Racing team deciding whether to race or not in the last session
- Car engine has blown out in 7 out of 24 past races
 - Should we risk an explosion and go bankrupt or race?
- A mechanic has a last-minute gut feeling that it might have to do with temperature
- Forecast for race: very cold day

Space Shuttle *Challenger* disaster

On January 28, 1986, the [Space Shuttle *Challenger*](#) broke apart 73 seconds into its flight, killing all seven crew members aboard. The spacecraft disintegrated 46,000 feet (14 km) above the Atlantic Ocean, off the coast of [Cape Canaveral](#), Florida, at 11:39 a.m. [EST](#) (16:39 [UTC](#)). It was the first fatal accident involving an [American spacecraft](#) while in flight.

The mission, designated [STS-51-L](#), was the tenth flight for the [orbiter](#) and the twenty-fifth flight of the Space Shuttle fleet. The crew was scheduled to deploy a communications satellite and study [Halley's Comet](#) while they were in orbit, in addition to taking school teacher [Christa McAuliffe](#) into space. The latter resulted in a higher than usual media interest and coverage of the mission; the launch and subsequent disaster were seen live in many schools across the United States.

The cause of the disaster was the failure of the primary and secondary redundant [O-ring](#) seals in a joint in the shuttle's right [solid rocket booster](#) (SRB). The record-low temperatures on the morning of the launch had stiffened the rubber O-rings, reducing their ability to seal the joints. Shortly after liftoff, the seals were breached, and hot pressurized gas from within the SRB leaked through the joint and burned through the aft attachment strut connecting it to the [external propellant tank](#) (ET), then into the tank itself. The [collapse](#) of the ET's internal structures and the rotation of the SRB that followed threw the shuttle

Space Shuttle *Challenger* disaster

Challenger's [solid rocket boosters](#) fly uncontrollably after the breakup of the [external tank](#) separated them from the shuttle stack. The remains of the orbiter and tank leave thin white contrails as they fall toward the Atlantic Ocean.

Introduction

- What is this course about?
- Expectations?

Introduction

- What is this course about?
- Expectations?
- **What is research? And why do we need to design it?**

Types of research

- *Theoretical* and *empirical* research
- *Qualitative* and *quantitative* empirical research

Empirical Research

- Goal: answer a question using empirical evidence
- How? exploiting **empirical variation**
- Research design is essentially knowing which variation to look at, how to measure it, how to analyze it, how to interpret it, etc – it's about inference

Empirical evidence and claims

REPORT

Analytic Thinking Promotes Religious Disbelief

WILL M. GERVAIS AND ARA NORENZAYAN [Authors Info & Affiliations](#)

Overthinking Religion?

Many theories of human cognition make a distinction between System I, which tends to be rapid and to rely on heuristics or rules of thumb, and System II, which tends to be more deliberative and analytic. This dual-process framework, within which both processes may operate simultaneously and competitively, has been used to explain a variety of situational influences upon decision-making. **Gervais and Norenzayan** (p. 493) studied the application of a dual-process framework to religious disbelief and found that triggering analytic thinking processes through a variety of experimental manipulations resulted in a tendency for subjects to report lower levels of religious belief.

Overthinking Religion? |

Abstract

Supplementary Material

Figures and Notes

eLetters (0)

We adopted three complementary strategies to test for robustness and generality. First, study 1 tested whether individual differences in the tendency to engage analytic thinking are associated with reduced religious belief. Second, studies 2 to 5 established causation by testing whether various experimental manipulations of analytic processing, induced subtly and implicitly, encourage religious disbelief. These manipulations of analytic processing included visual priming, implicit priming, and cognitive disfluency (18, 19). Third, across studies, we assessed religious belief using diverse measures that focused primarily on belief in and commitment to religiously endorsed supernatural agents. Samples consisted of participants from diverse cultural and religious backgrounds (20).

ipants only very rarely detected a connection between manipulations and religious belief measures (20).

Study 2 used a visual priming paradigm in which a sample of Canadian undergraduates rated their belief in God (from 0 to 100) after being randomly assigned to view four images (samples provided in Fig. 1) of either artwork depicting a reflective thinking pose (Rodin's

The Thinker; $N = 26$) or control artwork matched for surface characteristics like color and posture (*Discobolus* of Myron; $N = 31$). A pilot test with different participants ($N = 40$) revealed that this novel priming procedure significantly improved performance on a syllogistic reasoning task that measures analytic tendencies (20). In the present study, as hypothesized, viewing *The Thinker* significantly promoted religious

Replication crisis

 18 languages 

[Article](#) [Talk](#)

[Read](#) [Edit](#) [View history](#) [Tools](#) 

From Wikipedia, the free encyclopedia

This article is about an issue of scientific methodology. For the reproducibility crisis in humans, see [Male infertility crisis](#).

The **replication crisis** (also called the **replicability crisis** and the **reproducibility crisis**) is an ongoing [methodological](#) crisis in which the results of many scientific studies are difficult or impossible to [reproduce](#). Because the reproducibility of empirical results is an essential part of the [scientific method](#),^[2] such failures undermine the credibility of theories building on them and potentially call into question substantial parts of scientific knowledge.

The replication crisis is frequently discussed in relation to [psychology](#) and [medicine](#), where considerable efforts have been undertaken to reinvestigate classic results, to determine both their reliability and, if found unreliable, the reasons for the failure.^{[3][4]} Data strongly indicate that other [natural](#), and [social sciences](#) are affected as well.^[5]

The phrase *replication crisis* was coined in the early 2010s^[6] as part of a growing awareness of the problem. Considerations of causes and remedies have given rise to a new scientific discipline, [metascience](#),^[7] which uses methods of empirical research to examine empirical research practice.

Considerations about reproducibility fall into two categories. *Reproducibility* in the narrow sense refers to re-examining and validating the analysis of a given set of data. *Replication* refers to repeating the experiment or study to obtain new, independent data with the goal of reaching the same or similar conclusions.

Background [[edit](#)]

Why Most Published Research Findings Are False

Ioannidis et al.

Background: The replication crisis in psychology and medicine has led to a growing awareness of the problem. The authors of this paper argue that the crisis is not limited to psychology and medicine, but is a general problem of the scientific method. They argue that the crisis is caused by a combination of factors, including the pressure to publish, the incentives to publish, and the incentives to publish. They argue that the crisis is a general problem of the scientific method, and that it is not limited to psychology and medicine.

Methods: The authors of this paper conducted a meta-analysis of the literature on the replication crisis. They found that the replication crisis is a general problem of the scientific method, and that it is not limited to psychology and medicine.

Results: The authors of this paper found that the replication crisis is a general problem of the scientific method, and that it is not limited to psychology and medicine.

Conclusions: The authors of this paper conclude that the replication crisis is a general problem of the scientific method, and that it is not limited to psychology and medicine.

Keywords: Replication crisis, scientific method, psychology, medicine, meta-analysis.

Evaluating the replicability of social science experiments in *Nature* and *Science* between 2010 and 2015

Colin F. Camerer^{1,16}, Anna Dreber^{2,16}, Felix Holzmeister^{3,16}, Teck-Hua Ho^{4,16}, Jürgen Huber^{3,16}, Magnus Johannesson^{5,16}, Michael Kirchler^{3,5,16}, Gideon Nave^{6,16}, Brian A. Nosek^{7,8,16*}, Thomas Pfeiffer^{9,16}, Adam Altmejd^{10,2}, Nick Buttrick^{7,8}, Taizan Chan¹⁰, Yiling Chen¹¹, Eskil Forsell¹², Anup Gampa^{7,8}, Emma Heikensten², Lily Hummer⁸, Taisuke Imai¹³, Siri Isaksson², Dylan Manfredi⁶, Julia Rose³, Eric-Jan Wagenmakers¹⁴ and Hang Wu¹⁵

Being able to replicate scientific findings is crucial for scientific progress¹⁻¹⁵. We replicate 21 systematically selected experimental studies in the social sciences published in *Nature* and *Science* between 2010 and 2015¹⁶⁻³⁶. The replications follow analysis plans reviewed by the original authors and pre-registered prior to the replications. The replications are high powered, with sample sizes on average about five times higher than in the original studies. We find a significant effect in the same direction as the original study for 13 (62%) studies, and the effect size of the replications is on average about 50% of the original effect size. Replicability varies between 12 (57%) and 14 (67%) studies for complementary replicability indicators. Consistent with these results, the estimated true-

a significant effect in the same direction as the original studies for 61% of replications¹³. Both the RPP and the EERP had high statistical power to detect the effect sizes observed in the original studies. However, the effect sizes of published studies may be inflated even for true-positive findings owing to publication or reporting biases⁴⁰⁻⁴². As a consequence, if replications were well powered to detect effect sizes smaller than those observed in the original studies, replication rates might be higher than those estimated in the RPP and the EERP.

We provide evidence about the replicability of experimental studies in the social sciences published in the two most prestigious general science journals, *Nature* and *Science* (the Social Sciences Replication Project (SSRP)). Articles published in these

Violent storm kills six on Corsica as island raises new alert

By **Marc Angrand** and **Benoit Van Overstraeten**

August 18, 2022 8:34 PM GMT+2 · Updated a year ago

PARIS, Aug 18 (Reuters) - A violent and unexpected storm battered the French Mediterranean island of Corsica on Thursday, killing at least six people including a teenage girl, and meteorologists predicted more bad weather to come.

Hail, heavy rain and winds peaking at 224 km per hour (140 mph) swept the island early in the day. Two of the victims were killed when trees fell in campsites.

"Storms formed at sea will affect large parts of the western Corsica coast throughout the night from Thursday to Friday," Meteo France forecaster said.

- Interpretation
- Relevance
- **External validity**

Simplyfing

1. Formulate one (or more) RQ from a topic/problem
2. Develop a theoretical argument related to that RQ
3. Building on theory, think about what and how to measure
4. What variation are you going to look at? (and what data analysis tools do you need?)
5. What can you really learn from the results?

Let's go through an example

You are hired by the city government as a quantitative analyst to tackle the problem of **urban traffic in Madrid** and offer suggestions to improve it

Course logistics

- Tuesdays 18:00–21:00 (except last class)
- Seven sessions between September 17th and October 22nd
- Room 2.A.04 (Puerta de Toledo)

- My email: `francisco.villamil@uc3m.es`
- Office hours

Course logistics: evaluation

- Participation (15%)
- Research papers reviews (15%)
- Workshop group presentation (20%)
- Workshop feedback (10%)
- Final essay (40%)

Workshop and final essay

- In the workshop we will have around 12-15 slots (10 minute presentation & 10 feedback) so we need to do **group presentations**
 - We can adjust time once we know the final number of groups
- I do not mind if you do the final essay individually or in groups (max 3/4)
- Two good options:
 - Do a group presentation covering different strategies and individual essay with each of them
 - Do a group final essay

Final essay

- Get a topic or problem and go through all the steps in the research process
- No need to do data analyses or statistics (but you could show something if it's relevant)
- **Most important thing:** show me you understand how you can learn something about the topic from quantitative data, what different strategies you could use and what are the general and specific limitations of them
- Word limit: **5000 words** (we can talk in case of group essays)
 - Appendix obviously does not count
- **Deadline: October 30th, 23.59h** (exam week)

Course logistics: calendar

- 5 lectures (including today)
 - In sessions 2–4, we'll discuss a paper in the second half
 - You have to submit some comments/critique (5% each), **before** class (email or paper)
 - Final lecture on advanced topics, overview, and questions
- Last day: Workshop session (15h-21h)

Course logistics: calendar

- Sept 17: Introduction
- Sept 24: Elements of quantitative data
- Oct 1: Causality and experimental evidence
- Oct 8: Causal inference with observational data
- Oct 15: Advanced topics and overview
- Oct 22 (15h-21h): Workshop (double session)

Textbooks and resources

- Nick Huntington-Klein, **The Effect: An Introduction to Research Design and Causality** (Chapman and Hall/CRC, 2021).

Abstract

Weak state capacity is one of the most important explanations of civil conflict. Yet, current conceptualizations of state capacity typically focus only on the state while ignoring the relational nature of armed conflict. We argue that opportunities for conflict arise where relational state capacity is low, that is, where the state has less control over its subjects than its potential challengers. This occurs in ethnic groups that are poorly accessible from the state capital, but are internally highly interconnected. To test this argument, we digitize detailed African road maps and convert them into a road atlas akin to Google Maps. We measure the accessibility and internal connectedness of groups via travel times obtained from this atlas and simulate road networks for an instrumental variable design. Our findings suggest that low relational state capacity increases the risk of armed conflict in Africa.
