Introduction

Backgrounds & introduction

Introduction

- What is this course about?
- Expectations?

Introduction

- What is this course about?
- Expectations?

• What is research? And why do we need to design it?

Types of research

- Theoretical and empirical research
- Qualitative and quantitative empirical research

Empirical Research

- Goal: answer a question using empirical evidence
- How? exploiting empirical variation
- Research design is essentially knowing which variation to look at, how to measure it, how to analyze it, how to interpret it, etc – it's about inference

Empirical evidence and claims

Overthinking Religion?

king Religion?

Abstract ntary Material

ces and Notes

eLetters (0)

Many theories of human cognition make a distinction between System I, which tends to be rapid and to rely on heuristics or rules of thumb, and System II, which tends to be more deliberative and analytic. This dual-process framework, within which both processes may operate simultaneously and competitively, has been used to explain a variety of situational influences upon decision-making. Gervais and Norenzayan (p. 493) studied the application of a dual-process framework to religious disbelief and found that triggering analytic thinking processes through a variety of experimental manipulations resulted in a tendency for subjects to report lower levels of religious belief.

We adopted three complementary strategies to test for robustness and generality. First, study tested whether individual differences in the tendency to engage analytic thinking are associated with reduced religious belief. Second, studies 2 to 5 established causation by testing whether various experimental manipulations of analytic processing, induced subtly and implicitly, encourage religious disbelief. These manipulations of analytic processing included visual priming, implicit priming, and cognitive disfluency (18, 19). Third, across studies, we assessed religious belief using diverse measures that focused primarily on belief in and commitment to religiously endorsed supernatural agents. Samples consisted of participants from diverse cultural and religious backgrounds (20).

Fig. 1. Sample images of *The Thinker* (**left**) and *Discobolus* (**right**) used in study 2. The images shown here are similar to, but not the exact same ones used in the study. [Source: *Wikimedia*]

ipants only very rarely detected a connection between manipulations and religious belief measures (20).

Study 2 used a visual priming paradigm in which a sample of Canadian undergraduates rated their belief in God (from 0 to 100) after being randomly assigned to view four images (samples provided in Fig. 1) of either artwork depicting a reflective thinking pose (Rodin's

The Thinker; N = 26) or control artwork matched for surface characteristics like color and posture (Discobolus of Myron; N = 31). A pilot test with different participants (N = 40) revealed that this novel priming procedure significantly improved performance on a syllogistic reasoning task that measures analytic tendencies (20). In the present study, as hypothesized, viewing The Thinker significantly promoted religious

From Wikipedia, the free encyclopedia

This article is about an issue of scientific methodology. For the reproducibility crisis in humans, see Male infertility crisis.

The **replication crisis** (also called the **replicability crisis** and the **reproducibility crisis**) is an ongoing **methodological** crisis in which the results of many scientific studies are difficult or impossible to **reproduce**. Because the reproducibility of empirical results is an essential part of the **scientific method**, ^[2] such failures undermine the credibility of theories building on them and potentially call into question substantial parts of scientific knowledge.

The replication crisis is frequently discussed in relation to psychology and medicine, where considerable efforts have been undertaken to reinvestigate classic results, to determine both their reliability and, if found unreliable, the reasons for the failure. [3][4] Data strongly indicate that other natural, and social sciences are affected as well. [5]

The phrase *replication crisis* was coined in the early 2010s^[6] as part of a growing awareness of the problem. Considerations of causes and remedies have given rise to a new scientific discipline, metascience, which uses methods of empirical research to examine empirical research practice.

Considerations about reproducibility fall into two categories. *Reproducibility* in the narrow sense refers to reexamining and validating the analysis of a given set of data. *Replication* refers to repeating the experiment or study to obtain new, independent data with the goal of reaching the same or similar conclusions.

Being able to replicate scientific findings is crucial for scientific progress¹⁴⁵. We replicate 21 systematically selected experimental studies in the social sciences published in *Nature* and *Science* between 2010 and 2015^{16–36}. The replications follow analysis plans reviewed by the original authors and pre-registered prior to the replications. The replications are high powered, with sample sizes on average about five times higher than in the original studies. We find a significant effect in the same direction as the original study for 13 (62%) studies, and the effect size of the replications is on average about 50% of the original effect size. Replicability varies between 12 (57%) and 14 (67%) studies for complementary replicability indicators. Conscients with these results the actimated true

a significant effect in the same direction as the original studies for 61% of replications. Both the RPP and the EERP had high statistical power to detect the effect sizes observed in the original studies. However, the effect sizes of published studies may be inflated even for true-positive findings owing to publication or reporting biases. As a consequence, if replications were well powered to detect effect sizes smaller than those observed in the original studies, replication rates might be higher than those estimated in the RPP and the EERP.

We provide evidence about the replicability of experimental studies in the social sciences published in the two most prestigious general science journals, *Nature* and *Science* (the Social Sciences Replication Project (SSEP)) Articles published in these

Violent storm kills six on Corsica as island raises new alert

By Marc Angrand and Benoit Van Overstraeten

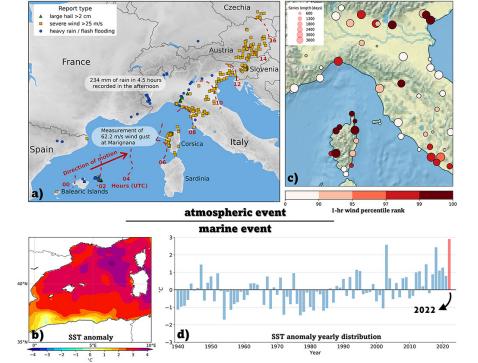

August 18, 2022 8:34 PM GMT+2 · Updated a year ago

PARIS, Aug 18 (Reuters) - A violent and unexpected storm battered the French Mediterranean island of Corsica on Thursday, killing at least six people including a teenage girl, and meteorologists predicted more bad weather to come.

Hail, heavy rain and winds peaking at 224 km per hour (140 mph) swept the island early in the day. Two of the victims were killed when trees fell in campsites.

"Storms formed at sea will affect large parts of the western Corsica coast throughout the night from Thursday to Friday," Meteo France forecaster said.

Opinions? How do you think it's done?

WHAT DATA CAN'T DO

When it comes to people—and policy—numbers are both powerful and perilous.

By Hannah Fry

March 22, 2021

> From **topic** (or problem) to the **research question**

> From **topic** (or problem) to the **research question**

Difference between motivation and question

- > From **topic** (or problem) to the **research question**
- Difference between motivation and question
- What are good & bad research questions?
 - → Answerable
 - → Relevant: importance and connection theory/empirics (*)

- > From **topic** (or problem) to the **research question**
- Difference between motivation and question
- What are good & bad research questions?
 - → Answerable
 - → Relevant: importance and connection theory/empirics (*)

Examples

- → What is the best Netflix show?
- → What can we do to help poor countries develop?
- → What are the shopping patterns of the Spanish population?
- \rightarrow (*) Do individuals from minorities support the use of violence?

> From **RQ** to **theory**

> From **RQ** to **theory**

• What is a theory? Importance

- > From **RQ** to **theory**
- What is a theory? Importance
- Arguments and mechanisms

- Good theories or arguments
 - → Testable
 - \rightarrow Credible

> From **theory** to **measurement**

- Concepts
- Operationalization in variables
- Measurement
- Unit of analysis

- > From **measurement** to **strategy**
- Once you have your variables measured, what variation are you going to look at?
 - → Think about how kids learn
- Descriptive and causal inference
- (Experiments) (*)

- > From **strategy** to **analyses**
- We're not covering this in this course
- This basically means choosing how you are going to analyze the variation you have
- Comparisons, models, statistics
- Question: what is the role of statistics in research design?

Research process in detail (6)

- > From **analyses** to **results** and back to **topic**
- Interpretation
- Relevance
- External validity

Simplyfing

- 1. Formulate one (or more) RQ from a topic/problem
- 2. Develop a theoretical argument related to that RQ
- 3. Building on theory, think about what and how to measure
- 4. What variation are you going to look at? (and what data analysis tools do you need?)
- 5. What can you really learn from the results?

Let's go through an example

You are hired by the city government as a quantitative analyst to tackle the problem of **urban traffic in Madrid** and offer suggestions to improve it

Course logistics

- Tuesdays 18:00–21:00 (most of the time)
- Seven sessions between September 12th and October 24th
- Room 2.A.04 (Puerta de Toledo)

- My email: francisco.villamil@uc3m.es
- Office hours

Course logistics: evaluation

- Participation (10%)
- Research papers reviews (15%)
- Workshop group presentation (20%)
- Workshop feedback (15%)
- Final essay (40%)

Workshop and final essay

- In the workshop we will have around 12-15 slots (10 minute presentation & 10 feedback) so we need to do group presentations
 - → We can adjust time once we know the final number of groups
- I do not mind if you do the final essay individually or in groups $(\max 3/4)$
- Two good options:
 - ightarrow Do a group presentation covering different strategies and individual essay with each of them
 - \rightarrow Do a group final essay

Final essay

- Get a topic or problem and go through all the steps in the research process
- No need to do data analyses or statistics (but you could show something if it's relevant)
- Most important thing: show me you understand how you can learn something about the topic from quantiative data, what different strategies you could use and what are the general and specific limitations of them
- Word limit: 5000 words (we can talk in case of group essays)
 - → Appendix obviously does not count
- Deadline: November 5th, 23.59h (exam week)

Course logistics: calendar

- 4 lectures (including today)
 - → In sessions 2–4, we'll discuss a paper in the second half
 - \rightarrow You have to submit some comments/critique (5% each), **before** class (email or paper)
- A workshop (double session)
- Final lecture on advanced topics, overview, and questions

Course logistics: calendar

- Sept 12th: Introduction
- Sept 19th: Elements of quantitative data
- Sept 26th: Causality and experimental evidence
- Oct 3rd: Causal inference with observational data
- Oct 10th: no class
- Oct 17th (15h-21h): Workshop (double session)
- Oct 24th (15h-18h): Advanced topics and overview

Your calendar in October

Abstract

Weak state capacity is one of the most important explanations of civil conflict. Yet, current conceptualizations of state capacity typically focus only on the state while ignoring the relational nature of armed conflict. We argue that opportunities for conflict arise where relational state capacity is low, that is, where the state has less control over its subjects than its potential challengers. This occurs in ethnic groups that are poorly accessible from the state capital, but are internally highly interconnected. To test this argument, we digitize detailed African road maps and convert them into a road atlas akin to Google Maps. We measure the accessibility and internal connectedness of groups via travel times obtained from this atlas and simulate road networks for an instrumental variable design. Our findings suggest that low relational state capacity increases the risk of armed conflict in Africa.
